

POWER SINK FOR 2 QUADRANT OPERATION options for SM800, SM1500, SM3000 and SM6000

The Power Sink Option permits the power supply to absorb bursts of power fed back to the unit. An internal module senses the status of power supply and sinks current across the output terminals, thus maintaining a constant output voltage.

The Power Sink Option allows a faster response when the power supply is step programmed to a lower voltage at small load conditions.

- Can absorb 10-20% of the unit power. For example, the SM6000 can absorb 700 W.
- Maintains output voltage setting regardless output power is positive or negative (source and sink)
- Ideal solution for supplying electric motors with PWM-speed control. These systems often return power to the power supply during a braking action
- Ideal solution for ATE systems requiring fast down programming at no load conditions
- Generation Automotive waveforms (fast)

Delta Elektronika Power Sinks

See table below for available Delta Elektronika Power Supplies with Power Sink option. All Power Sinks have electronically limited peak power and maximum current. The module shuts down in case of thermal overload (the unit itself continues operation). The overload condition is indicated with a LED on the front panel and with a status output.

Why does a DC Power Supply need a Power Sink

Modern Loads and Test-Systems become more demanding

In the past a DC power supply only needed to *deliver* power, now loads can *return* power. The only way to cope with this new challenge is integrating an electronic load in the power supply, called a Power Sink. Without the sink-capability the output voltage will start rising and get out of control.

Reverse Current

DC Motors are more and more controlled by a PWM (Pulse Width Modulation) circuit; the advantage is a flexible loss-less speed control. Car makers make use of this technique to make new solutions possible for pumps, electric steering, brakes, windscreen wipers, hybrid cars and more. Also energy is conserved, this means less heat dissipation. The special behavior of a PWM controlled motor is the return of power during a braking action. In fig. 1 you can see the typical load current, in phase I the motor accelerates; in phase II it has constant speed with a certain load and in phase III the motor brakes and the current becomes negative.

equipped power supply.
No voltage rise

Output under control

Normally the output circuit of a power supply is not designed to absorb current returned by the load; see the simplified circuit in fig. 2. The only path left for the negative load current is into the output capacitor C_o , so it will charge and the voltage will rise without any control from the power supply, following the formula $dv/dt = i/C$. To solve this problem a Power Sink is added, symbolised by the transistor in fig. 3, and integrated in the voltage control of the power supply. So the output voltage is kept to the desired voltage, whether the operation mode is sink or source. Dynamically the system reacts fast, see fig. 5. In this example the load current is switched between positive and negative (a harsh condition). On the output voltage only a slight variation is visible (upper trace). On a normal unit the voltage would rise uncontrolled, see fig. 4.

and negative

Fast Down Programming & Automotive

Test Systems require a test-time as short as possible. For each new item to be tested the voltage often has to be programmed down to zero. A normal power supply has a problem because it cannot quickly discharge the output capacitor C_o . The circuit in fig. 6 shows that only the load can discharge C_o .

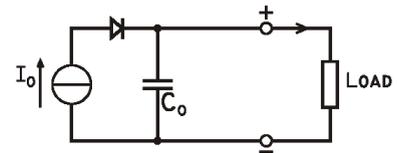

Fig. 6
Simplified output circuit
Normal power supply

A Power Sink as in fig. 7 will make it possible to do fast down-programming at light or no-load conditions. See fig. 8 and fig. 9 to compare the results. Also for generating fast simulation voltages, like the battery voltage of a starting car (ISO7637), a Power Sink is indispensable.
